Filter Options for Ink Jet Ink Production

For ink jet printing processes to work properly unwanted particles must be removed from the ink. Particles can take any number of forms from solids to agglomerated particles to gels. All particles have the potential to clog ink jet print head openings and cause print defects.

Particle sizes can range from visible (usually larger than 40 microns) to sub-micron sized. Removing them is usually done in stages, with larger particles removed first, then progressively smaller particles removed until the ink is free of contaminants that can affect performance.

Filters to remove large particles (particles larger than 5 microns) are first in the filter chain. Prefiltration steps are defined as those removing particles larger than those targeted by the final filtration step, but smaller than 5 microns. At the end of the filter chain are the “final” filters, those designed and chosen to remove the smallest unwanted particles.

Multiple filtration steps are used so as not to overload any single step. The filters can be located anywhere in the process, but are usually found at the introduction of ingredients, at intermediate stages of mixing/formulation, and again just before packaging.

Large Particle Removal
Removing large particles is often done as ingredients enter the process (housings marked “1”). This first filtration step removes large particles that could interfere with mixing and formulation processes. Standard depth filters are usually the most economical alternative for filtration at this stage. Standard depth filters are a self-supporting tube of fibers, usually made using polypropylene but also available in nylon. The depth filters capture particles in a wide range of sizes throughout the depth of the media. Depth filters with a pore size rating of 3 or 5 microns are most often used to capture larger particles.

Prefiltration and Final Filtration
Unwanted particles can be introduced to the process with ingredients from outside sources or even created as part of the process. Adding solid ingredients during formulation may result in undissolved particles. Impurities can also be carried downstream and through the process. Particles can also be created by chemical reactions used in the production process or from normal wear and tear on system components such as pumps and valves. The housing marked “3” is the final filter. That filter is often protected by a prefILTER (marked “2”) with a larger pore size rating.

The media and micron rating of the final filter and prefILTER are chosen based on the particle load of the ink and the size of the particles to be removed. If an ink specification requires particles larger than 1 micron to be removed, but allows particles smaller than 1 micron, then a depth media with a 1 micron or slightly smaller pore size rating is usually used. Inks requiring sub-micron size particles to be removed usually use membrane media with the pore size chosen based on the largest allowable particle.

Considerations for Pigmented Inks
The final filtration step in the simplified system shown in the figure has more than one filter. This is often the case for inks with very high particle loads, like pigmented inks. The biggest challenge in final filtration of pigmented inks is removing large particles while allowing most of the small particles to pass through the filters and remain evenly dispersed throughout the product. Depth filtration is the most often used technology, but selection of the specific filters is critical. The filtration results depend upon grind, dispersive agents and the specific filters used. It is important to note that different grinding systems can dramatically affect filter performance, and may result in excessive filter use and lower “small particle” yield. Contact Critical Process Filtration for assistance in evaluating filters for pigmented ink formulations.

Ordering Information

Cartridge order numbers have several variables from grade to media and pore size to end cap type. For example, Food & Beverage Grade, Polyethersulfone Membrane, 0.22 Micron Rating, with SS Support Ring, 20" Length, Silicone O-Rings, 2-226 O-Ring/Spear End Cap Configuration = FPS-2050000259.
